

RQ3 — the agents attend to the order-book features that matter, reallocate that attention by regime, and gain nothing from either

A. The agents are not ignoring the feature that was worth money
dashed line = share a single input would get if attention were spread evenly

B. In the simulated markets the policies are genuinely state-dependent;
on recorded books they collapse to a single constant

C. What the state-dependence buys: in every cell large enough to test, nothing distinguishable from zero — audit-valid agents only, since an unfinished order has no comparable cost

D. The same PPO agent reallocates attention by regime (35 agents, paired) toward spread and recent return, away from depth — and it changes no verdict

● PPO ● DQN — cell mean --- reference line (see panel) — 95% CI (panel D)
